

## **Description of Map Units**

## QUATERNARY SYSTEM

HOLOCENE

Holocene undifferentiated alluvium—Undifferentiated deposits of small upland streams: unconsolidated alluvial deposits of minor streams and creeks filling valleys incised into older deposits, with textures varying from gravelly sand to sandy mud.

Pmrl

Small river meander-belt deposits-Point bar deposits underlying the meander belts of small rivers.

Small river natural levee deposits—Deposits forming low natural levees flanking the meander belts of small rivers.

**Backswamp deposits**—Fine-grained Holocene deposits of rivers, accumulated in the flood basins between meander belts. Primarily unconsolidated mud and fine sand.

Distributary complex of Mississippi River meander belt 1- Natural levee deposits of the distributary course of Mississippi River meander belt 1.

**River channel remnants**—Sinuous tonal patterns interpreted to be abandoned river channels, buried beneath backswamp and natural levee deposits.

## PLEISTOCENE

LOESS-Eolian silt veneer of late Wisconsin age (Peoria Loess) mantling Pleistocene and older strata. Loess is shown where the total thickness of either or both loess units is 1 meter or greater.

**Upper Macon Ridge alloformation**—Sandy fluvial deposits formed by the Mississippi River during a braided depositional regime associated with the transport of glacial outwash. Sand and gravel channel and bar deposits that underlie a well-preserved braid belt that is sometimes are capped by Peoria Loess, loess-derived colluvium and/or silty alluvium, and/or fine-grained flood basin sediments. The Upper Macon Ridge alloformation is differentiated from the adjoining Lower Macon Ridge alloformation by a generally lower elevation and distinct crosscutting relationships. It is the stratigraphically higher subunit (geomor-phically lower subunit of Rittenour et al., 2007). Dating by the optically stimulated luminescence method (Rittenour et al. 2005, 2007) indicates that the two principal braid belts in Louisiana are both of middle Wisconsin age with the Upper Macon Ridge Alloformation slightly the younger.

Lower Macon Ridge alloformation—Sandy fluvial deposits formed by the Mississippi River during a braided depositional regime associated with the transport of glacial outwash. Sand and gravel channel and bar deposits that underlie a well-preserved braid belt that is that commonly are capped by Peoria Loess, loess-derived colluvium and/or silty alluvium, and/or fine-grained flood basin sediments. The Lower Macon Ridge alloformation in Louisiana is discontinu-ous along the eastern margin of Macon ridge and is the stratigraphically lower subunit (geomorphically higher subunit of Rittenour et al., 2007). Remnants consist of the southern end of Melville ridge and Walker ridge on the Natchez quadrangle and the Catahoula remnant further south.

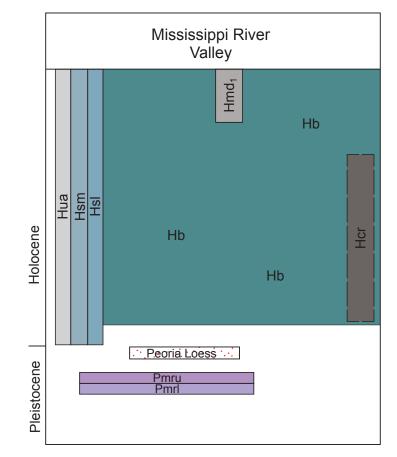

**Open Water Contact**—Includes inferred contacts. **Roads and Railroads** Streams **Topographic Contours**
